Indications for Cervical Myelography.

- Contraindication to MR.
- Equivocal MR finding.
- Dynamic or multipositional evaluation.

Roadblocks to Myelography.

- Contrast allergy-use Prednisone and Benadryl.
- Hold medications that lower the seizure threshold 48 hours prior to procedure.
- Coumadin-hold 5 days. Lovenox-Hold 24 hours prior to procedure.
- Uncooperative patient—education.
- Plavix and ASA are OK.

Informed consent and patient education.

- Most common complication-“post-puncture” headache. Smaller needles reduce incidence. Rest for 72 hours after procedure, slow progression to full activity.
- Risk of contrast allergy.
- Risk of seizure.
- Risk of cord injury; ensure patient cooperation.
- Nausea, vomiting, meningitis, musculoskeletal pain, bleeding, risk of infection, temporary or permanent pain or weakness secondary to nerve damage.

Patient preparation.

- Increased fluids 24 hours prior.
- Light meal 2 hours prior.
- Crackers prior to oral morphine to minimize gastric irritation.
- Hold seizure threshold meds 48 hrs, take usual meds, especially pain meds.
- Arrange light duty for 72 hrs post procedure to minimize headache.

Sedation.

- Versed 6mg **PO**.
- Morphine Sulfate 10mg **PO**. May substitute Demerol 50-75mg if severe pain or morphine contraindicated.
- Toradol 30-60mg **IM** post procedure for headache, prn.

Our Imaging Suite.

Positioning for needle placement.

- Left lateral decubitus position.
- Shoulders aligned and head on stack of folded pillow cases.
- Under fluoro, superimpose jaws.

Relevant anatomy.

- Access should be attempted only at the posterior 1/3rd of the canal at C1-C2.
- Localize this area using fluoroscopy and anesthetize the overlying area.

Relevant anatomy.

- Access should be attempted only at the posterior 1/3rd of the canal at C1-C2.
- Localize this area using fluoroscopy and anesthetize the overlying area.

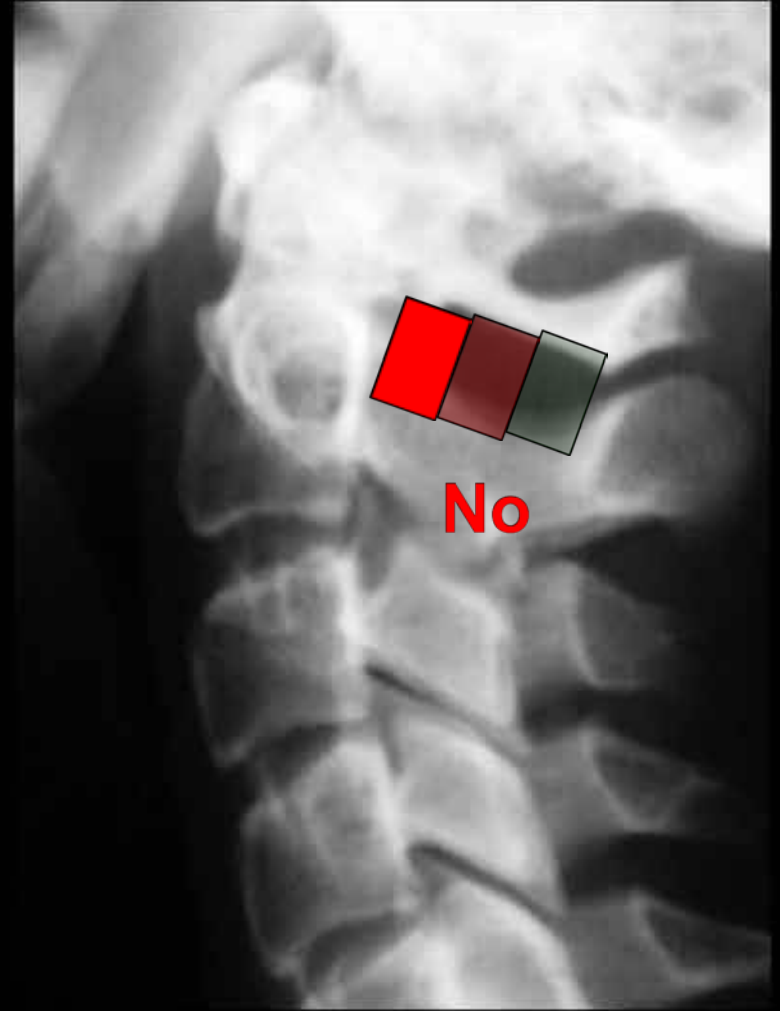

Relevant anatomy.

- Access should be attempted only at the posterior 1/3rd of the canal at C1-C2.

Relevant anatomy.

- Access should be attempted only at the posterior 1/3rd of the canal at C1-C2.
- Localize this area using fluoroscopy and anesthetize the overlying area.

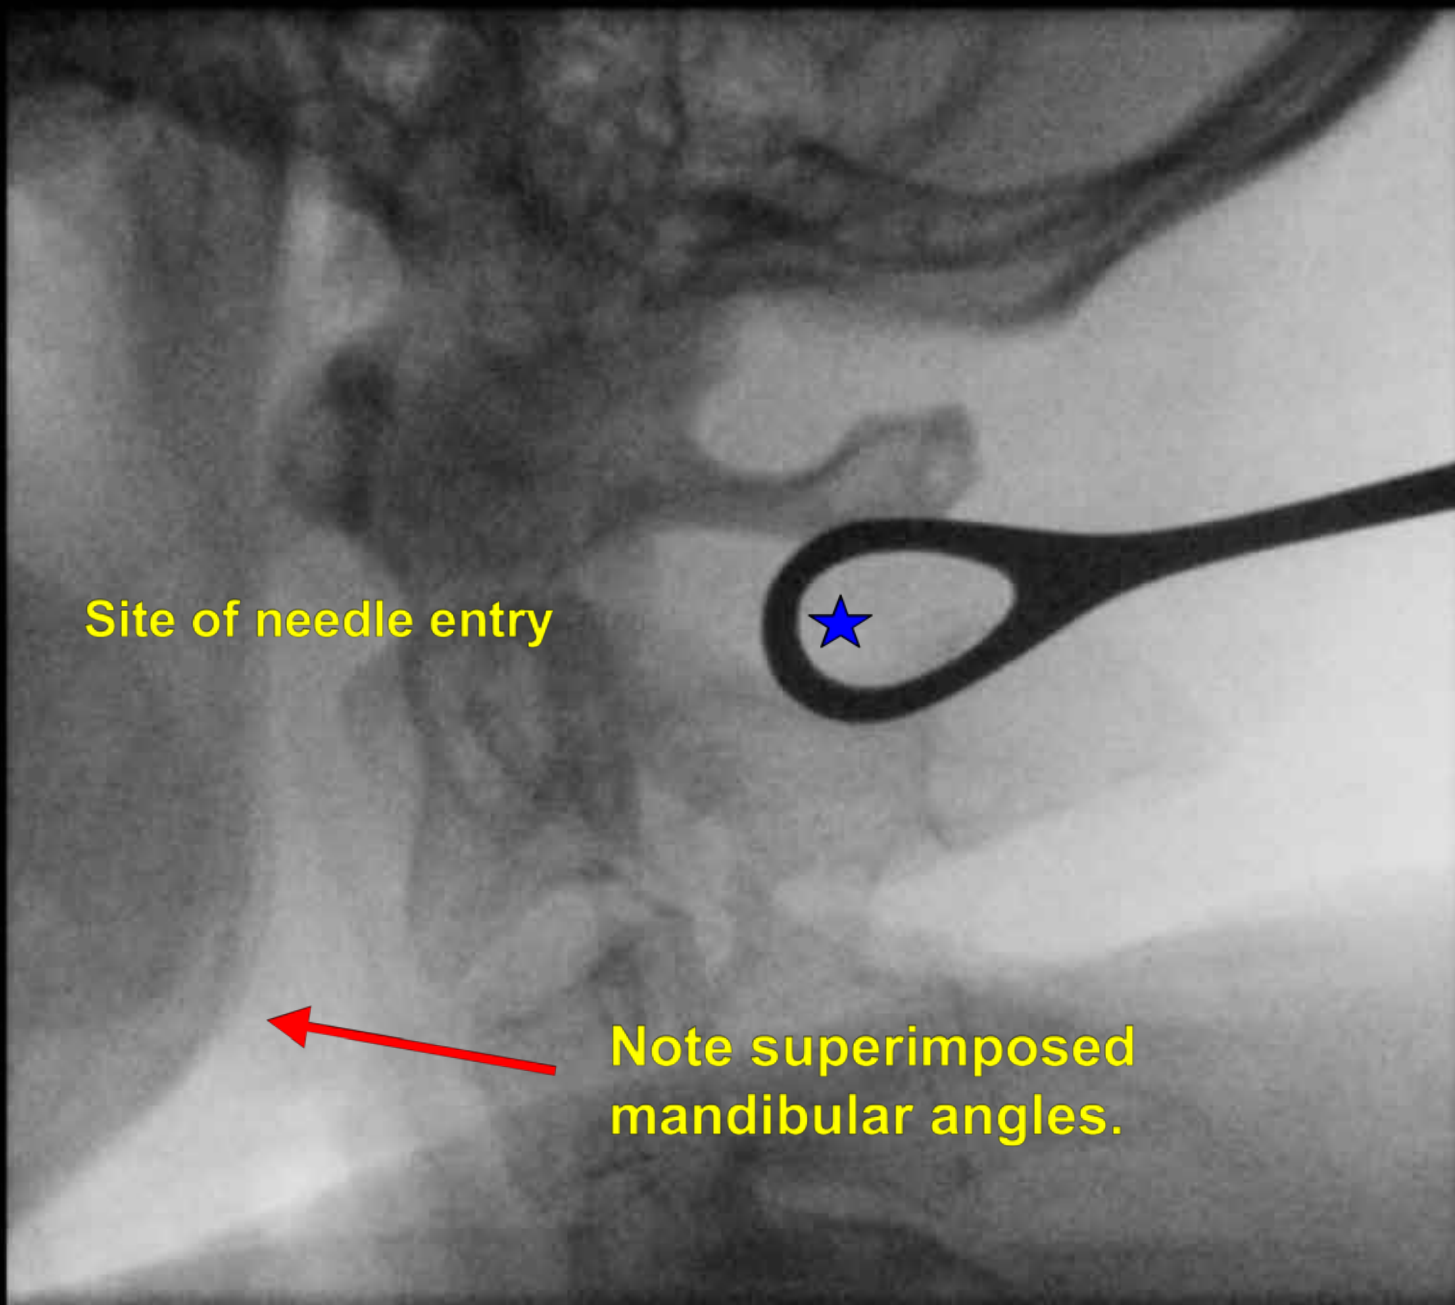

Relevant anatomy.

- Access should be attempted only at the posterior 1/3rd of the canal at C1-C2.
- Localize this area using fluoroscopy and anesthetize the overlying area.

Marking the patient under fluoroscopy.

After site selection.

1. Advance needle under fluoroscopy until sub-arachnoid space is accessed (past the dural resistance).

2. Confirm free-flowing CSF.

3. Inject contrast and image.

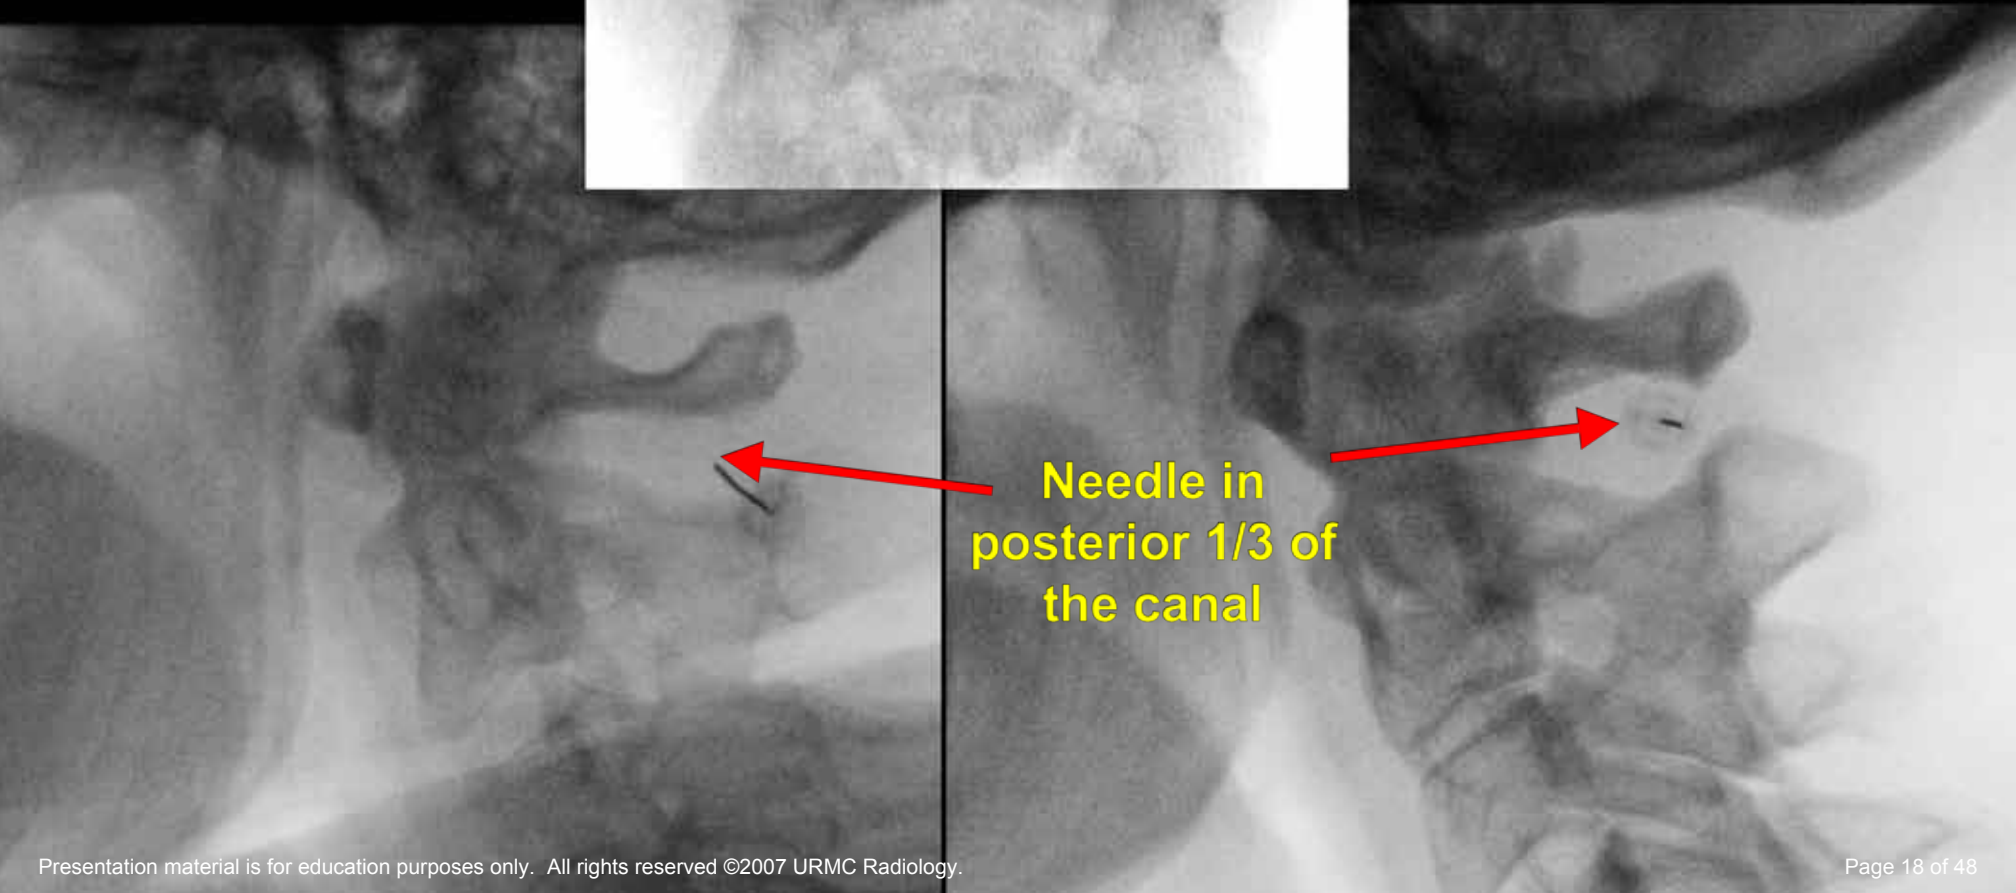

Correct needle placement.

Midline
needle tip
on AP

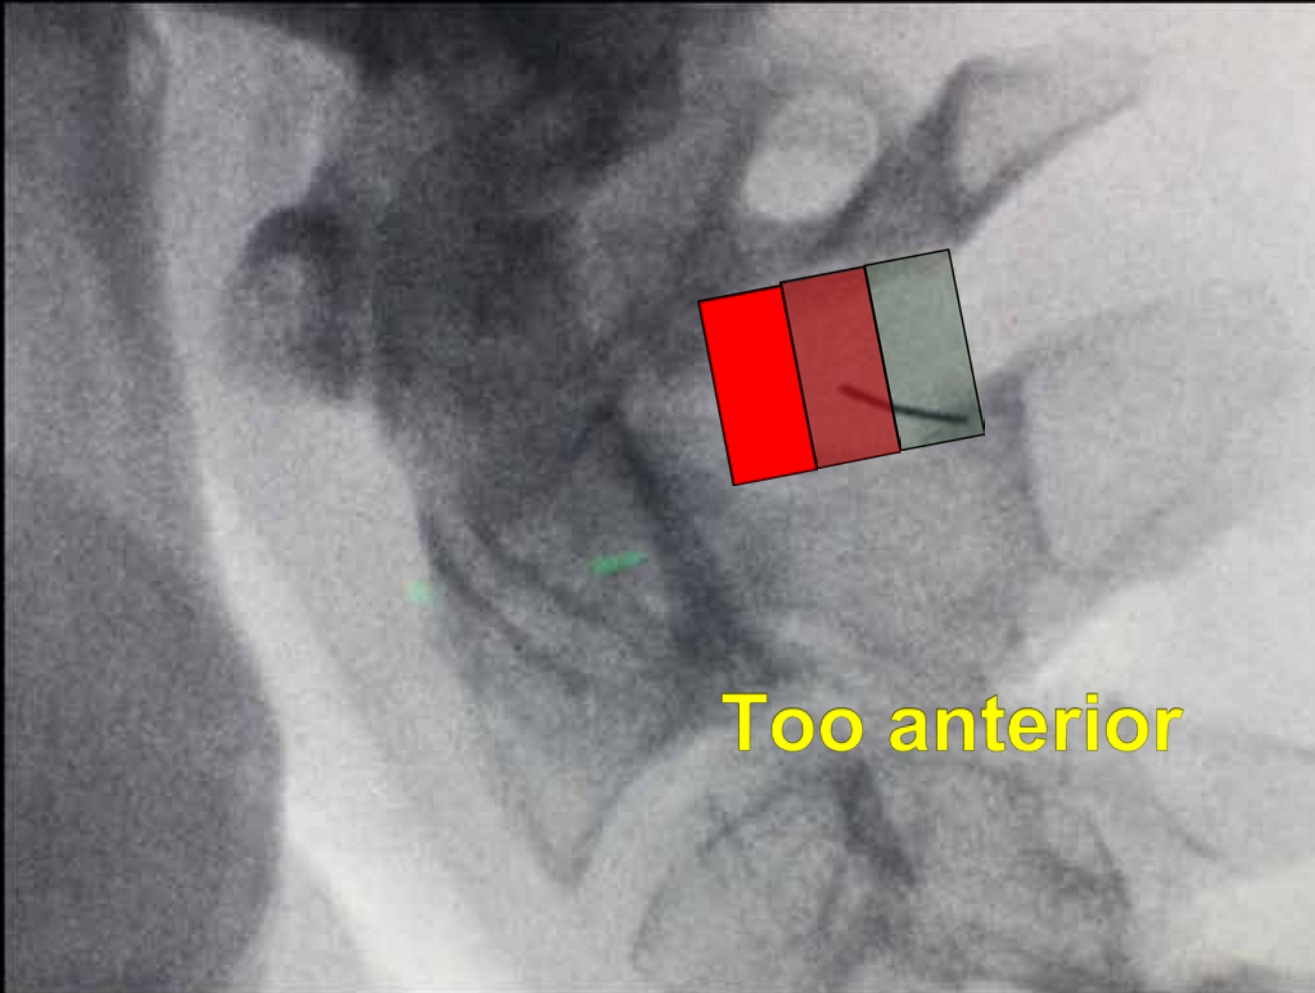

Needle in
posterior 1/3 of
the canal

Incorrect needle positioning.

Incorrect needle positioning.

Before contrast injection.

- Visualization of CSF must be free flowing in lateral & prone position.
- Needle should be midline in AP projection.
- **DO NOT INJECT IF:**
 - *Needle is not midline on AP projection.
 - *CSF is not free flowing.

Before contrast injection.

**Cord contrast injection, not
needle placement in the cord,
is the mechanism for severe
complications.**

- Visualization of CSF must be free flowing in lateral & prone position.
- Needle should be midline in AP projection.
- **DO NOT INJECT IF:**

***Needle is not midline on AP projection. *CSF is not free flowing.**

CSF Flow.

Contrast injection.

Imaging protocol.

View

Post-procedure protocol.

- Rest in recliner chair or bed.
- Avoid heavy lifting, bending or stretching for 72 hours.
- Someone to monitor patient for 24 hours.
- Increase fluids.
- Monitor access site for signs of infection.
- NSAIDS for headache.

Managing complications.

- Most common-neck spasm from positioning; immediate warm compresses and Toradol.
- Increased need for narcotics due to cervical pathology.
- Nausea and vomiting-symptomatic management, IV hydration.

Managing complications. Post-procedure headache.

- More frequent with lumbar puncture and Trendelenberg position.
- Migraine-medication.
- Inflammatory-NSAIDS, +/- warm compress.

Interesting case.

Interesting case.

Myelographic block.

Cessation of contrast flow.

Myelographic
block.

Cessation of contrast
flow.

Myelographic Block.

Cessation of contrast flow.

case.

Truncation
of nerve
sheath.

Interesting
case.

Interesting
case.

Interesting case.

Unilateral narrowing of central canal.

Double contrast sign – due to thecal indentation seen in profile.

Interesting case.

Interesting case.

Leakage/pooling
of contrast.

**Leakage/pooling
of contrast.**

Interesting case.

Pseudomeningocele.

Traumatic avulsion.

Pseudomeningocele.

Interesting case.

Leakage/pooling of contrast.

Summary.

- In experienced hands, patients will have a comfortable and safe experience.
- Myelography can be a valuable diagnostic tool.
- Post-procedure symptoms can be easily managed.
